ICNARC report on COVID-19 in critical care:
England, Wales and Northern Ireland

12 November 2021

This report presents analyses of data on patients critically ill with confirmed COVID-19, reported to ICNARC up to 23:59 on 11 November 2021, from critical care units participating in the Case Mix Programme (the national clinical audit covering all NHS adult, general intensive care and combined intensive care/high dependency units in England, Wales and Northern Ireland, plus some additional specialist and non-NHS critical care units) and increasing numbers of surge/other areas providing critical care.

Data are reported separately for patients critically ill with confirmed COVID-19 either at or after the admission to critical care:

- admitted from 1 May 2021 to date; and
- admitted from 1 September 2020 to 30 April 2021.

For additional reporting on patients admitted up to 31 August 2020, please see the report dated 5 July 2021 available from https://www.icnarc.org/Our-Audit/Audits/Cmp/Reports.

Please note that adult critical care units in Scotland, paediatric intensive care units and neonatal intensive care units do not participate in the Case Mix Programme.

Reporting process

Critical care units/areas participating in the Case Mix Programme are asked to:

- log a case with ICNARC by submitting a record, with minimal data, as soon as they have an admission with confirmed COVID-19;
- resubmit data, including first 24-hour physiology, as soon as possible after the end of the first 24 hours in critical care;
- resubmit data for the whole critical care stay, including critical care outcome and organ support, when the patient leaves critical care; and
- submit final data when the patient leaves acute hospital.

* Please see individual notes for Figures/Tables.
ICNARC have logged data for 11,333 admissions of 9935 patients critically ill with confirmed COVID-19, either at or after admission to critical care, admitted from 1 May 2021 to date in England, Wales and Northern Ireland. Of these, data covering the first 24 hours of critical care have been submitted to ICNARC for 9676 patients (Figure 1). Of the 9935 total patients, 8831 have outcomes reported and 1104 patients were last reported as still receiving critical care. These patients are compared with a cohort of 25,841 patients with confirmed COVID-19 admitted from 1 September 2020 to 30 April 2021.

**Figure 1. Numbers of patients with data included in this report and outstanding * **

Numbers of critically ill patients with confirmed COVID-19 admitted from 1 May 2021 to date with data included in this report and outstanding *.

* Please note that 24-hour data are considered outstanding when a case was logged at least 48 hours previously and outcome data are considered outstanding when 24-hour data have been received and at least 10 days have elapsed since the admission to critical care.
The geographical distribution of patients critically ill with confirmed COVID-19 admitted from 1 May 2021 to date by NHS region is shown in Figure 2 and compared with those admitted from 1 September 2020 to 30 April 2021. Of the patients included in this week’s report, 844 patients were admitted to critical care within the past 14 days (29 October 2021 to 11 November 2021). The geographical spread of these patients is shown in Figure 3.

**Figure 2. Geographical distribution**
Geographical distribution of patients critically ill with confirmed COVID-19 admitted from 1 May 2021 to date compared with those admitted from 1 September 2020 to 30 April 2021 by NHS region.

**Figure 3. Geographical distribution – past 14 days**
Geographical distribution of patients critically ill with confirmed COVID-19 admitted during the past 14 days by NHS region.
The numbers of new patients, cumulative numbers of patients and numbers of patients in critical care by date are shown in Figures 4-13. Please note that these figures are affected by a variable lag time for submission of data.

Figure 14 shows the average daily number of patients in critical care for each month over the past five years. For 2020-21, this is broken down into the numbers of: elective admissions (not COVID-19) – those admitted directly following elective or scheduled surgery or for a planned medical procedure; non-elective admissions (not COVID-19); confirmed COVID-19 admitted to a critical care unit; and confirmed COVID-19 managed in a surge area outside of an established critical care unit.

© ICNARC 2021

Figure 14. Average daily number of patients in critical care by month, 2016-2021 *

* Please note that data for patients without COVID-19 are submitted by participating critical care units either monthly or quarterly. Values have been adjusted for coverage.

$ Not all surge patients are identifiable from critical care unit data and not all surge areas are covered.
The numbers of admissions with acute myocardial infarction, stroke, trauma and self-harm (with drugs or other substances) recorded as primary or secondary reason for admission to critical care (with or without recording of COVID-19 as the other reason for admission) are shown in Figures 15 to 18.

* Please note that data for patients without COVID-19 are submitted by participating critical care units either monthly or quarterly. Values have been adjusted for coverage.

Figure 17. Number of admissions with trauma by month, 2016-2021 *

* Please note that data for patients without COVID-19 are submitted by participating critical care units either monthly or quarterly. Values have been adjusted for coverage.
Figure 18. Number of admissions with self-harm (drugs or other substances) by month, 2016-2021 *

* Please note that data for patients without COVID-19 are submitted by participating critical care units either monthly or quarterly. Values have been adjusted for coverage.
Figure 19 shows the total numbers of admissions to critical care over the past five years by month of admission reported as due to pneumonia (not COVID-19), compared with the numbers with confirmed COVID-19. Figure 20 shows the number of these pneumonia admissions that were specifically coded as due to influenza. Note that not all admissions due to influenza will be coded as viral pneumonia (influenza) as if the organism has not yet been identified, then these will likely be coded under pneumonia (no organism isolated).

Figure 19. Number of admissions with pneumonia (not COVID-19) by month, 2016-2021 *, compared with confirmed COVID-19 during 2020

* Please note that data for patients without COVID-19 are submitted by participating critical care units either monthly or quarterly. Values have been adjusted for coverage.
Figure 20. Number of admissions with viral pneumonia (influenza) by month, 2016-2021 *

* Please note that data for patients without COVID-19 are submitted by participating critical care units either monthly or quarterly. Values have been adjusted for coverage.
Patient characteristics

Characteristics of patients critically ill with confirmed COVID-19 admitted from 1 May 2021 to date are summarised in Tables 1-3 and compared with those admitted from 1 September 2020 to 30 April 2021.

* Please see Definitions on page 87. Indicators of acute severity are based on data from the first 24 hours of critical care.

† Derived from the arterial blood gas with the lowest \(\text{PaO}_2\) during the first 24 hours of critical care.
The distribution of age and sex for patients critically ill with confirmed COVID-19 admitted from 1 May 2021 to date is presented in Figure 21.

**Figure 21. Age and sex distribution**

Age and sex distribution of patients critically ill with confirmed COVID-19 admitted from 1 May 2021 to date.
The distribution of ethnicity for patients critically ill with confirmed COVID-19 admitted from 1 May 2021 to date, compared with a local population matched on 2011 census ward for residence of patients critically ill with COVID-19, is presented in Figure 22.

![Figure 22. Ethnicity distribution compared with the local population](image)

Ethnicity distribution of patients critically ill with confirmed COVID-19 admitted from 1 May 2021 to date compared with the local population (linked to 2011 census ward).
The distribution of Index of Multiple Deprivation (IMD) for patients critically ill with confirmed COVID-19 admitted from 1 May 2021 to date, compared with the general population, is presented in Figure 23.

**Figure 23. Index of Multiple Deprivation * distribution compared with the general population**

Index of Multiple Deprivation (IMD) * distribution of patients critically ill with confirmed COVID-19 admitted from 1 May 2021 to date compared with the general population.

* Please see Definitions on page 87.
The distribution of the percentage of patients critically ill with confirmed COVID-19 admitted from 1 May 2021 to date by the urban/rural classification of their usual residence, compared with the age-matched general population (Office for National Statistics 2020), is presented in Figure 24.

**Figure 24. Urban/rural * distribution compared with the age-matched general population**

Urban/rural * distribution of patients critically ill with confirmed COVID-19 admitted from 1 May 2021 to date compared with the age-matched general population.

* Please see Definitions on page 87.
The distribution of body mass index (BMI) for patients critically ill with confirmed COVID-19 admitted from 1 May 2021 to date, compared with an age- and sex-matched population (from the Health Survey for England 2018), is presented in Figure 25.

**Figure 25. Body mass index * distribution compared with the age- and sex-matched general population**

Body mass index (BMI) * distribution of patients critically ill with confirmed COVID-19 admitted from 1 May 2021 compared with the age- and sex-matched general population (Health Survey for England 2018).

* Please see Definitions on page 87.
Patient characteristics – invasively ventilated first 24 hours

Characteristics of patients critically ill with confirmed COVID-19 and receiving invasive ventilation during the first 24 hours in critical care admitted from 1 May 2021 to date are summarised in Tables 4-6 and compared with those admitted from 1 September 2020 to 30 April 2021.

Inter-hospital critical care transfers

From 1 May 2021 to date, there have been 761 inter-hospital critical care transfers of 649 patients with confirmed COVID-19, of which 452 transfers of 424 patients were classified as being for comparable critical care. The percentage of transfers by month is shown in Figure 26.

Figure 26. Inter-hospital critical care transfers

Percentage of critical care admissions with confirmed COVID-19 that were transfers between critical care units in different hospitals by month of admission and reason for transfer.

* Please see Definitions on page 87. Dashed line indicates incomplete month.
Critical care outcomes have been received for 8831 (of 9935) patients critically ill with confirmed COVID-19 admitted from 1 May 2021 to date. Of these, 2622 have died and 6209 have been discharged from critical care (Figures 27). The remaining 1104 were last reported to still be receiving critical care.

Pregnancy

The numbers of critically ill women with confirmed COVID-19 reported to be currently and recently pregnant on admission to critical care are shown in Figure 28 and, as a percentage of women aged 16-49 years, in Figure 29. The percentage of all critically ill patients with confirmed COVID-19 that were currently or recently pregnant women by region and time period are shown in Figure 30. Characteristics and critical care outcome of women aged 16-49 years by pregnancy status are reported in Table 27 for women admitted from 1 May 2021 to date and compared with women admitted from 1 September 2020 to 30 April 2021 in Table 28.

* Please see Definitions on page 87. Indicators of acute severity are based on data from the first 24 hours of critical care. N/A denotes not available.

† Derived from the arterial blood gas with the lowest PaO₂ during the first 24 hours of critical care.
A Kaplan-Meier plot of in-hospital survival to 28 days following admission to critical care for patients critically ill with confirmed COVID-19 admitted from 1 May 2021 to date is shown in Figure 31 and compared with those admitted from 1 September 2020 to 30 April 2021 and up to 31 August 2020.

Figure 31. In-hospital survival to 28 days following admission to critical care
Kaplan-Meier survival analysis for patients critically ill with confirmed COVID-19. Patients last reported to be still receiving critical care censored on the most recent date of data submission by the treating unit. Patients discharged from acute hospital within 28 days assumed to survive to 28 days. Please note that these survival curves are not adjusted for differences in patient characteristics (see Tables 1-3).
Comparison of adjusted 28-day in-hospital mortality between time periods

Figure 32 shows hazard ratios comparing 28-day in-hospital mortality for patients critically ill with confirmed COVID-19 admitted from 1 May 2021 to 30 July 2021 compared with those admitted from 1 September 2020 to 30 April 2021 across patient subgroups. Hazard ratios are calculated from Cox proportional hazards models adjusted for all the subgroup variables shown and for physiology measured during the first 24 hours of critical care. Dashed vertical line shows the overall adjusted hazard ratio between the time periods.
Figure 32. Hazard ratios comparing patients admitted May 2021 to July 2021 vs September 2020 to April 2021 by patient subgroup *

Hazard ratios from Cox proportional hazards models adjusted for all subgroup variables plus the following physiological measurements from the first 24 hours of critical care: highest heart rate; highest respiratory rate; highest blood lactate concentration; highest serum creatinine; highest serum urea; lowest platelet count; and neutrophil count associated with the lowest white blood cell count.
90-day in-hospital outcome

A Kaplan-Meier plot of in-hospital survival to 90 days following admission to critical care for patients critically ill with confirmed COVID-19 admitted from 1 May 2021 to date is shown in Figure 33 and compared with those admitted from 1 September 2020 to 30 April 2021 and up to 31 August 2020.

Figure 33. In-hospital survival to 90 days following admission to critical care
Kaplan-Meier survival analysis for patients critically ill with confirmed COVID-19. Patients last reported to be still receiving critical care censored on the most recent date of data submission by the treating unit. Patients discharged from acute hospital within 90 days assumed to survive to 90 days. Please note that these survival curves are not adjusted for differences in patient characteristics (see Tables 1-3).
Monthly trends in characteristics for patients critically ill with confirmed COVID-19 are shown for key summary statistics in Figures 34-36 and as full distributions in Figures 37-39.

Figure 40 shows the monthly number of new patients critically ill with confirmed COVID-19 from March 2020 until the last complete month and the corresponding 28-day in-hospital mortality, indicating the months in which information became available identifying steroids (Dexamethasone) and IL-6 inhibitors (Tocilizumab) as effective treatments for critically ill patients. Figures 41-43 show monthly variation in patient characteristics relating to ventilation and timing of critical care compared with the change in mortality.

Figure 40. Number of admissions and 28-day in-hospital mortality by month

Number of new admissions and 28-day in-hospital mortality for patients critically ill with confirmed COVID-19 by month of admission to critical care.

Estimates of 28-day in-hospital mortality based on Kaplan-Meier survival analysis. Patients last reported to be still receiving critical care censored on the most recent date of data submission by the treating unit. Patients discharged from acute hospital within 28 days assumed to survive to 28 days. Please note that these estimates are not adjusted for changes in patient characteristics (see Tables 1-3).
Figure 41. PaO\textsubscript{2}/FiO\textsubscript{2} and 28-day in-hospital mortality by month

Percentage of patients in most severe PaO\textsubscript{2}/FiO\textsubscript{2} category (≤ 13.3 kPa) and 28-day in-hospital mortality for patients critically ill with confirmed COVID-19 by month of admission to critical care.

Estimates of 28-day in-hospital mortality based on Kaplan-Meier survival analysis. Patients last reported to be still receiving critical care censored on the most recent date of data submission by the treating unit. Patients discharged from acute hospital within 28 days assumed to survive to 28 days. Please note that these estimates are not adjusted for changes in patient characteristics (see Tables 1-3).
Figure 42. Invasive ventilation first 24 hours and 28-day in-hospital mortality by month

Percentage of patients receiving invasive ventilation during the first 24 hours in critical care and 28-day in-hospital mortality for patients critically ill with confirmed COVID-19 by month of admission to critical care.

Estimates of 28-day in-hospital mortality based on Kaplan-Meier survival analysis. Patients last reported to be still receiving critical care censored on the most recent date of data submission by the treating unit. Patients discharged from acute hospital within 28 days assumed to survive to 28 days. Please note that these estimates are not adjusted for changes in patient characteristics (see Tables 1-3).
Figure 43. Prior hospital length of stay and 28-day in-hospital mortality by month

Percentage of patients with a hospital stay of 2 or more days before admission to critical care and 28-day in-hospital mortality for patients critically ill with confirmed COVID-19 by month of admission to critical care.

Estimates of 28-day in-hospital mortality based on Kaplan-Meier survival analysis. Patients last reported to be still receiving critical care censored on the most recent date of data submission by the treating unit. Patients discharged from acute hospital within 28 days assumed to survive to 28 days. Please note that these estimates are not adjusted for changes in patient characteristics (see Tables 1-3).
Weekly trends in recent admissions – COVID-19

Weekly trends in characteristics for patients critically ill with confirmed COVID-19 from 1 May 2021 onwards are shown for key summary statistics in Figures 44-46 and as full distributions in Figures 47-49.

$ Derived from the arterial blood gas with the lowest PaO₂ during the first 24 hours of critical care.
Changes in mortality over time may be driven in part by changes in the characteristics of patients admitted to critical care, i.e. their average predicted risk of death at the time of admission (due to illness severity, comorbidities or demographic risk factors). To adjust for changes in the predicted risk of death over time, we developed a risk prediction model for 28-day in-hospital mortality using all patients critically ill with COVID-19 first admitted from 1 March to 30 April 2020 (Ferrando-Vivas et al, 2021). We validated the model using both the same patients and patients admitted from 1 May to 31 August 2020.

Figure 50 shows observed 28-day in-hospital mortality by month compared with predicted 28-day in-hospital mortality based on the characteristics and outcomes of patients admitted during March and April 2020. Although predicted mortality has varied, most recently decreasing substantially as the patients admitted to critical care have become younger on average, the observed mortality has remained lower than predicted since May 2020.

Figure 50. Risk-adjusted 28-day in-hospital mortality
Kaplan-Meier based estimates of observed 28-day in-hospital mortality for patients critically ill with confirmed COVID-19 compared with predicted mortality from a prediction model developed using data for patients admitted during March and April 2020. If the observed outcomes are as predicted by the model, then we would expect the observed mortality to lie within the 95% reference range 19 times out of 20 and within the 99.8% reference range 998 times out of 1000.
Definitions

Reason for transfer between critical care units is categorised as:

- Comparable critical care: transfer for similar care as provided in the transferring critical care unit
- Repatriation: returning a patient to their original unit, hospital or area
- More-specialist critical care: transfer for specialist critical care not available in the transferring critical care unit

Critical care transfer groups are groups of local critical care units developed to reduce the number of long distance transfers that take place and to ensure that transfers are contained within the critical care network or, by special agreement, between hospitals at the borders of adjacent networks.

Ethnicity is recorded using the ethnic category codes from the 2001 census and grouped as:

- White: White – British; White – Irish; White – any other
- Mixed: Mixed – white and black Caribbean; Mixed – white and black African; Mixed – white and Asian; Mixed – any other
- Asian: Asian or Asian British – Indian; Asian or Asian British – Pakistani; Asian or Asian British – Bangladeshi; Asian or Asian British – any other
- Black: Black or black British – Caribbean; Black or black British – African; Black or black British – any other
- Other: Other ethnic group – Chinese; Any other ethnic group
- Not stated or not recorded

Index of Multiple Deprivation (IMD) is based on the patient’s usual residential postcode (assigned at the level of Lower Layer Super Output Area) according to:

- English Index of Multiple Deprivation 2019 for postcodes in England
- Welsh Index of Multiple Deprivation 2019 for postcodes in Wales
- Northern Ireland Multiple Deprivation Measure 2017 for postcodes in Northern Ireland

Urban/rural classification is based on the patient’s usual residential postcode (assigned at the level of Output Area) and categorised according to 2011 census categories as:

- Urban: the majority of the population lives within settlements with a population of more than 10,000 people, subcategorised according to dwelling densities for every 100m x 100m square and the density in squares at varying distances around each square as either Major conurbation, Minor conurbation, or City or town
- Rural: the majority of the population lives within settlements with a population of less than 10,000 people (combining the categories Town and fringe, Village, and Hamlet or isolated dwellings)

Body mass index is calculated as the weight in kilograms divided by the height in metres squared. Weight and height values may have been measured or estimated.
Dependency prior to admission to acute hospital is assessed as the best description for the dependency of the patient in the two weeks prior to admission to acute hospital and prior to the onset of the acute illness, i.e. “usual” dependency. It is assessed according to the amount of personal assistance they receive with daily activities (bathing, dressing, going to the toilet, moving in/out of bed/chair, continence and eating).

Very severe comorbidities must have been evident within the six months prior to critical care and documented at or prior to critical care:

- Cardiovascular: symptoms at rest
- Respiratory: shortness of breath with light activity or home ventilation
- Renal: renal replacement therapy for end-stage renal disease
- Liver: biopsy-proven cirrhosis, portal hypertension or hepatic encephalopathy
- Metastatic disease: distant metastases
- Haematological malignancy: acute or chronic leukaemia, multiple myeloma or lymphoma
- Immunocompromise: chemotherapy, radiotherapy or daily high dose steroid treatment in previous six months, HIV/AIDS or congenital immune deficiency

Invasive ventilation during the first 24 hours was defined as mechanical ventilation (identified by the recording of a ventilated respiratory rate, indicating that all or some of the breaths or a portion of the breaths were delivered by a mechanical device) and sedation (receiving continuous or intermittent doses of agents to produce and maintain a continuous decreased level of consciousness with or without paralysing agents) at any time during the first 24 hours and not reported as having zero days of advanced respiratory support.

Organ support is recorded as the number of calendar days (00:00-23:59) on which the support was received at any time, defined as:

- Advanced respiratory: invasive ventilation, BPAP via trans-laryngeal tube or tracheostomy, CPAP via trans-laryngeal tube, extracorporeal respiratory support
- Basic respiratory: >50% oxygen by face mask, close observation due to potential for acute deterioration, physiotherapy/suction to clear secretions at least two-hourly, recently extubated after a period of mechanical ventilation, mask/hood CPAP/BPAP, non-invasive ventilation, CPAP via a tracheostomy, intubated to protect airway
- Advanced cardiovascular: multiple IV/rhythm controlling drugs (at least one vasoactive), continuous observation of cardiac output, intra-aortic balloon pump, temporary cardiac pacemaker
- Basic cardiovascular: central venous catheter, arterial line, single IV vasoactive/ rhythm controlling drug
- Renal: acute renal replacement therapy, renal replacement therapy for chronic renal failure where other organ support is received
- Liver: management of coagulopathy and/or portal hypertension for acute on chronic hepato-cellular failure or primary acute hepato-cellular failure
- Neurological: central nervous system depression sufficient to prejudice airway, invasive neurological monitoring, continuous IV medication to control seizures, therapeutic hypothermia
